

# Machine Learning Engineer Nanodegree

## Reinforcement Learning

### Project: Train a Smartcab to Drive

Welcome to the fourth project of the Machine Learning Engineer Nanodegree! In this notebook, template code has already been provided for you to aid in your analysis of the *Smartcab* and your implemented learning algorithm. You will not need to modify the included code beyond what is requested. There will be questions that you must answer which relate to the project and the visualizations provided in the notebook. Each section where you will answer a question is preceded by a '**Question X**' header. Carefully read each question and provide thorough answers in the following text boxes that begin with '**Answer:**'. Your project submission will be evaluated based on your answers to each of the questions and the implementation you provide in `agent.py`.

**Note:** Code and Markdown cells can be executed using the **Shift + Enter** keyboard shortcut. In addition, Markdown cells can be edited by typically double-clicking the cell to enter edit mode.

## Getting Started

In this project, you will work towards constructing an optimized Q-Learning driving agent that will navigate a *Smartcab* through its environment towards a goal. Since the *Smartcab* is expected to drive passengers from one location to another, the driving agent will be evaluated on two very important metrics: **Safety** and **Reliability**. A driving agent that gets the *Smartcab* to its destination while running red lights or narrowly avoiding accidents would be considered **unsafe**. Similarly, a driving agent that frequently fails to reach the destination in time would be considered **unreliable**. Maximizing the driving agent's **safety** and **reliability** would ensure that *Smartcabs* have a permanent place in the transportation industry.

**Safety** and **Reliability** are measured using a letter-grade system as follows:

Grade	Safety	Reliability
A+	Agent commits no traffic violations, and always chooses the correct action.	Agent reaches the destination in time for 100% of trips.
A	Agent commits few minor traffic violations, such as failing to move on a green light.	Agent reaches the destination on time for at least 90% of trips.
B	Agent commits frequent minor traffic violations, such as failing to move on a green light.	Agent reaches the destination on time for at least 80% of trips.
C	Agent commits at least one major traffic violation, such as driving through a red light.	Agent reaches the destination on time for at least 70% of trips.
D	Agent causes at least one minor accident, such as turning left on green with oncoming traffic.	Agent reaches the destination on time for at least 60% of trips.
F	Agent causes at least one major accident, such as driving through a red light with cross-traffic.	Agent fails to reach the destination on time for at least 60% of trips.

To assist evaluating these important metrics, you will need to load visualization code that will be used later on in the project. Run the code cell below to import this code which is required for your analysis.

In [3]:

```
# Import the visualization code
import visuals as vs

# Pretty display for notebooks
%matplotlib inline
```

## Understand the World

Before starting to work on implementing your driving agent, it's necessary to first understand the world (environment) which the *Smartcab* and driving agent work in. One of the major components to building a self-learning agent is understanding the characteristics about the agent, which includes how the agent operates. To begin, simply run the `agent.py` agent code exactly how it is -- no need to make any additions whatsoever. Let the resulting simulation run for some time to see the various working components. Note that in the visual simulation (if enabled), the **white vehicle** is the *Smartcab*.

### Question 1

In a few sentences, describe what you observe during the simulation when running the default `agent.py` agent code. Some things you could consider:

- *Does the Smartcab move at all during the simulation?*
- *What kind of rewards is the driving agent receiving?*
- *How does the light changing color affect the rewards?*

**Hint:** From the `/smartcab/` top-level directory (where this notebook is located), run the command

```
'python smartcab/agent.py'
```

**Answer:**

- . Smartcab doesn't move during the simulation
- . Driver agent is getting large negative(-4 or lesser) rewards when not moving in green lights, small positive rewards(1.5+ or so ) when not moving in red lights.
- . when agent is stationary(not learning), green light gives negative reward and red light gives positive reward.

## Understand the Code

In addition to understanding the world, it is also necessary to understand the code itself that governs how the world, simulation, and so on operate. Attempting to create a driving agent would be difficult without having at least explored the "*hidden*" devices that make everything work. In the `/smartcab/` top-level directory, there are two folders: `/logs/` (which will be used later) and `/smartcab/`. Open the `/smartcab/` folder and explore each Python file included, then answer the following question.

### Question 2

- *In the `agent.py` Python file, choose three flags that can be set and explain how they change the simulation.*
- *In the `environment.py` Python file, what `Environment` class function is called when an agent performs an action?*
- *In the `simulator.py` Python file, what is the difference between the `'render_text()'` function and the `'render()'` function?*
- *In the `planner.py` Python file, will the `'next_waypoint()'` function consider the North-South or East-West direction first?*

## Answer:

. Below are 3 randomly chosen parameters :

**log\_metrics** : when set True, will start writing log files

**n\_test** : it is number of testing trials to be performed

**display** : when set True , will display the simulation graphics

. "act" function is called when agent performs an action.

. In the simulator.py Python file, render\_text() function renders log info on terminal & render() function renders data on GUI.

. In the planner.py Python file, the 'next\_waypoint()' function consider East-West direction first.

---

## Implement a Basic Driving Agent

The first step to creating an optimized Q-Learning driving agent is getting the agent to actually take valid actions. In this case, a valid action is one of None, (do nothing) 'left' (turn left), 'right' (turn right), or 'forward' (go forward). For your first implementation, navigate to the 'choose\_action()' agent function and make the driving agent randomly choose one of these actions. Note that you have access to several class variables that will help you write this functionality, such as 'self.learning' and 'self.valid\_actions'. Once implemented, run the agent file and simulation briefly to confirm that your driving agent is taking a random action each time step.

## Basic Agent Simulation Results

To obtain results from the initial simulation, you will need to adjust following flags:

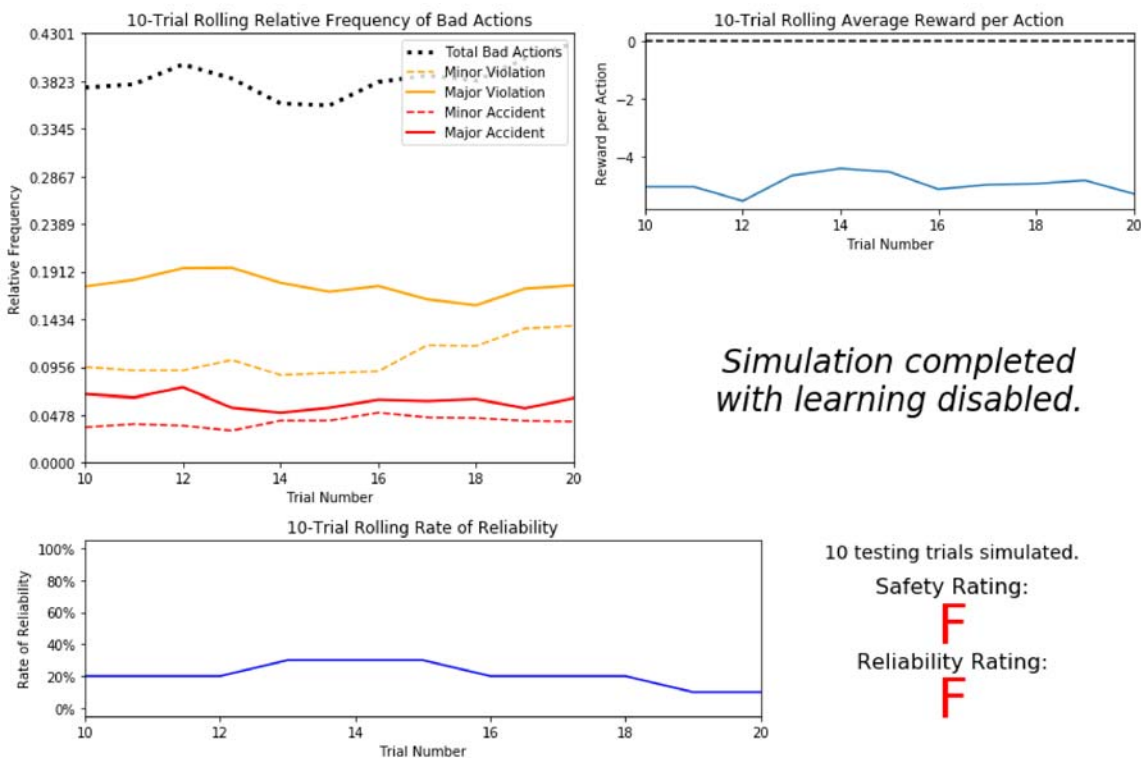

- 'enforce\_deadline' - Set this to True to force the driving agent to capture whether it reaches the destination in time.
- 'update\_delay' - Set this to a small value (such as 0.01) to reduce the time between steps in each trial.
- 'log\_metrics' - Set this to True to log the simulation results as a .csv file in /logs/.
- 'n\_test' - Set this to '10' to perform 10 testing trials.

Optionally, you may disable the visual simulation (which can make the trials go faster) by setting the 'display' flag to False. Flags that have been set here should be returned to their default setting when debugging. It is important that you understand what each flag does and how it affects the simulation!

Once you have successfully completed the initial simulation (there should have been 20 training trials and 10 testing trials), run the code cell below to visualize the results. Note that log files are overwritten when identical simulations are run, so be careful with what log file is being loaded! Run the agent.py file after setting the flags from projects/smartcab folder instead of projects/smartcab/smartcab.

In [3]:

```
# Load the 'sim_no-learning' log file from the initial simulation results
vs.plot_trials('sim_no-learning.csv')
```

### Question 3

Using the visualization above that was produced from your initial simulation, provide an analysis and make several observations about the driving agent. Be sure that you are making at least one observation about each panel present in the visualization. Some things you could consider:

- How frequently is the driving agent making bad decisions? How many of those bad decisions cause accidents?
- Given that the agent is driving randomly, does the rate of reliability make sense?
- What kind of rewards is the agent receiving for its actions? Do the rewards suggest it has been penalized heavily?
- As the number of trials increases, does the outcome of results change significantly?
- Would this Smartcab be considered safe and/or reliable for its passengers? Why or why not?

**Answer:** . Avg relative frequency of bad decisions is above ~0.3823, i.e. ~38% and above . There are ~ 10% accidents caused (major and minor combined).

. It is not reliable because it is driving randomly. Reliability Rating F makes perfect sense. Reliability Rate is also very low (~20%).

. Agent has received negative rewards. Yes, penalized heavily.

. No. Outcome doesn't change significantly when agent is not in learning mode.

. Safety rating is F and so is Reliability Rating. Hence this smartcab is not safe/reliable. Because actions are random and agent is not learning.

---

## Inform the Driving Agent

The second step to creating an optimized Q-learning driving agent is defining a set of states that the agent can occupy in the environment. Depending on the input, sensory data, and additional variables available to the driving agent, a set of states can be defined for the agent so that it can eventually *learn* what action it should take when occupying a state. The condition of 'if state then action' for each state is called a **policy**, and is ultimately what the driving agent is expected to learn. Without defining states, the driving agent would never understand which action is most optimal -- or even what environmental variables and conditions

### Identify States

Inspecting the 'build\_state()' agent function shows that the driving agent is given the following data from the environment:

- 'waypoint', which is the direction the *Smartcab* should drive leading to the destination, relative to the *Smartcab*'s heading.
- 'inputs', which is the sensor data from the *Smartcab*. It includes
  - 'light', the color of the light.
  - 'left', the intended direction of travel for a vehicle to the *Smartcab*'s left. Returns None if no vehicle is present.
  - 'right', the intended direction of travel for a vehicle to the *Smartcab*'s right. Returns None if no vehicle is present.
  - 'oncoming', the intended direction of travel for a vehicle across the intersection from the *Smartcab*. Returns None if no vehicle is present.
- 'deadline', which is the number of actions remaining for the *Smartcab* to reach the destination before running out of time.

### Question 4

*Which features available to the agent are most relevant for learning both **safety** and **efficiency**? Why are these features appropriate for modeling the Smartcab in the environment? If you did not choose some features, why are those features not appropriate? Please note that whatever features you eventually choose for your agent's state, must be argued for here. That is: your code in agent.py should reflect the features chosen in this answer.*

NOTE: You are not allowed to engineer new features for the smartcab.

**Answer:** . For safety , I have chosen "light" and "oncoming". I believe it is necessary information to avoid accidents and violations.

. For reliability, I have chosen "waypoint", because it guides smartcab about which direction to move forward on.

. In my previous submission - I excluded both "left" and "right". However, This time I am considering "left". As per review comments and as per US traffic laws, car can turn RIGHT if there is no incoming traffic from left. I was confused on this point previously, because - in India - its left side drive on the road, and hence opposite rule applies. So if we had to design this as per India rules, I would have chosen "right". That's why in previous submission, I included both "left" and "right" while turning the agent. It added to my functional learning.

. "deadline" is also not chosen for this simulation. as it doesn't impact safety or reliability at this stage of code.

## Define a State Space

When defining a set of states that the agent can occupy, it is necessary to consider the *size* of the state space. That is to say, if you expect the driving agent to learn a **policy** for each state, you would need to have an optimal action for *every* state the agent can occupy. If the number of all possible states is very large, it might be the case that the driving agent never learns what to do in some states, which can lead to uninformed decisions. For example, consider a case where the following features are used to define the state of the *Smartcab*:

```
('is_raining', 'is_foggy', 'is_red_light', 'turn_left', 'no_traffic',  
'previous_turn_left', 'time_of_day').
```

How frequently would the agent occupy a state like (False, True, True, True, False, False, '3AM')? Without a near-infinite amount of time for training, it's doubtful the agent would ever learn the proper action!

## Question 5

*If a state is defined using the features you've selected from **Question 4**, what would be the size of the state space? Given what you know about the environment and how it is simulated, do you think the driving agent could learn a policy for each possible state within a reasonable number of training trials?*

**Hint:** Consider the *combinations* of features to calculate the total number of states!

**Answer:**

Below are possible values of state attributes :

waypoint : forward, left, right

light : red, green

left : None, left, right, forward

oncoming : None, forward, left, right

so size of space =  $3 \times 2 \times 4 \times 4 = 96$

## Update the Driving Agent State

For your second implementation, navigate to the `'build_state()'` agent function. With the justification you've provided in **Question 4**, you will now set the `'state'` variable to a tuple of all the features necessary for Q-Learning. Confirm your driving agent is updating its state by running the agent file and simulation briefly and note whether the state is displaying. If the visual simulation is used, confirm that the updated state corresponds with what is seen in the simulation.

**Note:** Remember to reset simulation flags to their default setting when making this observation!

---

## Implement a Q-Learning Driving Agent

The third step to creating an optimized Q-Learning agent is to begin implementing the functionality of Q-Learning itself. The concept of Q-Learning is fairly straightforward: For every state the agent visits, create an entry in the Q-table for all state-action pairs available. Then, when the agent encounters a state and performs an action, update the Q-value associated with that state-action pair based on the reward received and the iterative update rule implemented. Of course, additional benefits come from Q-Learning, such that we can have the agent choose the *best* action for each state based on the Q-values of each state-action pair possible. For this project, you will be implementing a *decaying*,  $\epsilon$ -greedy Q-learning algorithm with *no* discount factor. Follow the implementation instructions under each **TODO** in the agent functions.

Note that the agent attribute `self.Q` is a dictionary: This is how the Q-table will be formed. Each state will be a key of the `self.Q` dictionary, and each value will then be another dictionary that holds the *action* and *Q-value*. Here is an example:

```
{ 'state-1': {
    'action-1' : Qvalue-1,
    'action-2' : Qvalue-2,
    ...
},
  'state-2': {
    'action-1' : Qvalue-1,
    ...
},
  ...
}
```

Furthermore, note that you are expected to use a *decaying  $\epsilon$  (exploration) factor*. Hence, as the number of trials increases,  $\epsilon$  should decrease towards 0. This is because the agent is expected to learn from its behavior and begin acting on its learned behavior. Additionally, The agent will be tested on what it has learned after  $\epsilon$  has passed a certain threshold (the default threshold is 0.05). For the initial Q-Learning implementation, you will be implementing a linear decaying function for  $\epsilon$ .

## Q-Learning Simulation Results

To obtain results from the initial Q-Learning implementation, you will need to adjust the following flags and setup:

- 'enforce\_deadline' - Set this to True to force the driving agent to capture whether it reaches the destination in time.
- 'update\_delay' - Set this to a small value (such as 0.01) to reduce the time between steps in each trial.
- 'log\_metrics' - Set this to True to log the simulation results as a .csv file and the Q-table as a .txt file in /logs/.
- 'n\_test' - Set this to '10' to perform 10 testing trials.
- 'learning' - Set this to 'True' to tell the driving agent to use your Q-Learning implementation.

In addition, use the following decay function for  $\epsilon$ :

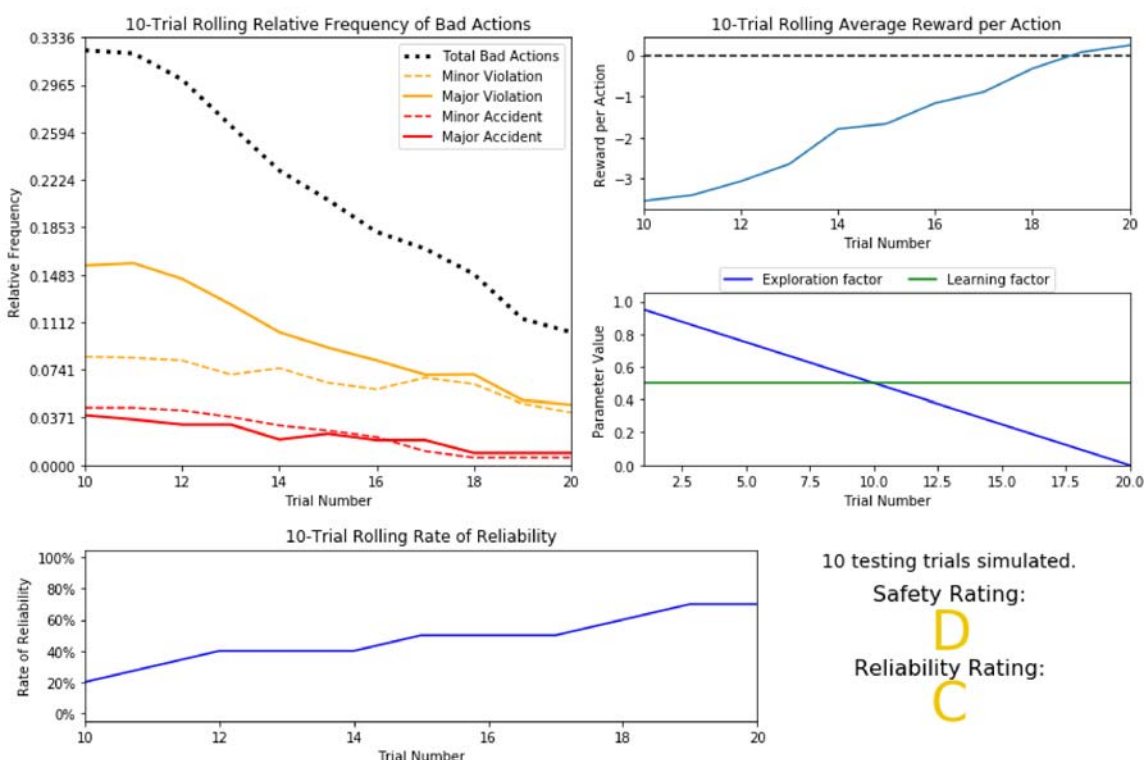

$$\epsilon_{t+1} = \epsilon_t - 0.05, \text{ for trial number } t$$

If you have difficulty getting your implementation to work, try setting the 'verbose' flag to True to help debug. Flags that have been set here should be returned to their default setting when debugging. It is important that you understand what each flag does and how it affects the simulation!

Once you have successfully completed the initial Q-Learning simulation, run the code cell below to visualize the results. Note that log files are overwritten when identical simulations are run, so be careful with what log file is being loaded!

In [4]:

```
# Load the 'sim_default-learning' file from the default Q-Learning simulation
vs.plot_trials('sim_default-learning.csv')
```

## Question 6

Using the visualization above that was produced from your default Q-Learning simulation, provide an analysis and make observations about the driving agent like in **Question 3**. Note that the simulation should have also produced the Q-table in a text file which can help you make observations about the agent's learning. Some additional things you could consider:

- *Are there any observations that are similar between the basic driving agent and the default Q-Learning agent?*
- *Approximately how many training trials did the driving agent require before testing? Does that number make sense given the epsilon-tolerance?*
- *Is the decaying function you implemented for  $\epsilon$  (the exploration factor) accurately represented in the parameters panel?*
- *As the number of training trials increased, did the number of bad actions decrease? Did the average reward increase?*
- *How does the safety and reliability rating compare to the initial driving agent?*

### Answer:

. After all trials, the frequency of bad decisions is in case of default Q-Learning agent is ~11%. In Basic driving agent, it was ~38%. Reliability has improved from ~20% to gradual 60% +. Reward per action has increased significantly compared to Basic agent after trials are completed, Exploration factor graph suggests linear decay of epsilon as per configured decay policy (0.05).

. Agent required ~20 trials before testing. It visible from epsilon, decay and tolerance function also , where epsilon (1) is decaying linearly with rate of 0.05 till it hits tolerance level of 0.05 and starts test runs.

. Yes, the exploration factor line in the parameter value panel is suggesting the decay function that is implemented. As visible - epsilon, decay and tolerance function is linear- where slope is 1 and intercept is -0.05.

. Yes. As the number of trails increased, number of bad action decreased. Reward is also consistently increasing with every run.

. Reliability rating improved from F to A+, and Safety rating improved from F to D. It makes sense because agent is in better state of learning than initial driving agent.

---

## Improve the Q-Learning Driving Agent

The third step to creating an optimized Q-Learning agent is to perform the optimization! Now that the Q-Learning algorithm is implemented and the driving agent is successfully learning, it's necessary to tune settings and adjust learning parameters so the driving agent learns both **safety** and **efficiency**. Typically this step will require a lot of trial and error, as some settings will invariably make the learning worse. One thing to keep in mind is the act of learning itself and the time that this takes: In theory, we could allow the agent to learn for an incredibly long amount of time; however, another goal of Q-Learning is to *transition from experimenting with unlearned behavior to acting on learned behavior*. For example, always allowing the agent to perform a random action during training (if  $\epsilon = 1$  and never decays) will certainly make it *learn*, but never let it *act*. When improving on your Q-Learning implementation, consider the implications it creates and whether it is logistically sensible to make a particular adjustment.

## Improved Q-Learning Simulation Results

To obtain results from the initial Q-Learning implementation, you will need to adjust the following flags and setup:

- 'enforce\_deadline' - Set this to True to force the driving agent to capture whether it reaches the destination in time.
- 'update\_delay' - Set this to a small value (such as 0.01) to reduce the time between steps in each trial.
- 'log\_metrics' - Set this to True to log the simulation results as a .csv file and the Q-table as a .txt file in /logs/.
- 'learning' - Set this to 'True' to tell the driving agent to use your Q-Learning implementation.
- 'optimized' - Set this to 'True' to tell the driving agent you are performing an optimized version of the Q-Learning implementation.

Additional flags that can be adjusted as part of optimizing the Q-Learning agent:

- 'n\_test' - Set this to some positive number (previously 10) to perform that many testing trials.
- 'alpha' - Set this to a real number between 0 - 1 to adjust the learning rate of the Q-Learning algorithm.
- 'epsilon' - Set this to a real number between 0 - 1 to adjust the starting exploration factor of the Q-Learning algorithm.
- 'tolerance' - set this to some small value larger than 0 (default was 0.05) to set the epsilon threshold for testing.

Furthermore, use a decaying function of your choice for  $\epsilon$  (the exploration factor). Note that whichever function you use, it **must decay to 'tolerance' at a reasonable rate**. The Q-Learning agent will not begin testing until this occurs. Some example decaying functions (for  $t$ , the number of trials):

$$\epsilon = a^t, \text{ for } 0 < a < 1 \quad \epsilon = \frac{1}{t^2} \quad \epsilon = e^{-at}, \text{ for } 0 < a < 1 \quad \epsilon = \cos(at), \text{ for } 0 < a <$$

You may also use a decaying function for  $\alpha$  (the learning rate) if you so choose, however this is typically less common. If you do so, be sure that it adheres to the inequality  $0 \leq \alpha \leq 1$ .

If you have difficulty getting your implementation to work, try setting the 'verbose' flag to True to help debug. Flags that have been set here should be returned to their default setting when debugging. It is important that you understand what each flag does and how it affects the simulation!

Once you have successfully completed the improved Q-Learning simulation, run the code cell below to visualize the results. Note that log files are overwritten when identical simulations are run, so be careful with what log file is being loaded!

In [6]:

```
# Load the 'sim_improved-Learning' file from the improved Q-Learning simulation
vs.plot_trials('sim_improved-learning.csv')
```

## Question 7

Using the visualization above that was produced from your improved Q-Learning simulation, provide a final analysis and make observations about the improved driving agent like in **Question 6**. Questions you should answer:

- What decaying function was used for epsilon (the exploration factor)?
- Approximately how many training trials were needed for your agent before beginning testing?
- What epsilon-tolerance and alpha (learning rate) did you use? Why did you use them?
- How much improvement was made with this Q-Learner when compared to the default Q-Learner from the previous section?
- Would you say that the Q-Learner results show that your driving agent successfully learned an appropriate policy?
- Are you satisfied with the safety and reliability ratings of the Smartcab?

## Answer:

As part of tuning parameters - I followed below approach :

(1) First play with epsilon, and decay equations mentioned in the notebook. Find an optimum one.

(2) Try with lower and upper tolerance levels than default.

After multiple trials, I found that none of the combinations did better than default Q Learning. However, I also realised that same output is not regenerated, even if same script is run again and again. Looking at the code and understanding the environment - its clear that randomness is playing a role.

So at this stage, I went back to Default Q learning epsilon, decay and tolerance.

Then I started changing learning rate alpha. Although its difficult to reproduce same results twice, I realised by looking at graphs that learning rate more than 0.8 resulted into more bad decisions after ~160 trails. So I kept alpha to 0.8.

Even at this stage, overall safety and reliability didnt improve to acceptable level. I tried with Linear decay factor 0.005, so that agent is trained more before testing. Now it is taking 30 trials before testing. That resulted in acceptable results.

Total bad decisions are decreasing, rewards are increasing and reliability is also increasing.

I am satisfied with the overall safety and reliability. Based on the lectures and reading the question 9 - I believe that it can be further improved with optimal discount factor Gamma.

## Define an Optimal Policy

Sometimes, the answer to the important question "*what am I trying to get my agent to learn?*" only has a theoretical answer and cannot be concretely described. Here, however, you can concretely define what it is the agent is trying to learn, and that is the U.S. right-of-way traffic laws. Since these laws are known information, you can further define, for each state the *Smartcab* is occupying, the optimal action for the driving agent based on these laws. In that case, we call the set of optimal state-action pairs an **optimal policy**. Hence, unlike some theoretical answers, it is clear whether the agent is acting "incorrectly" not only by the reward (penalty) it receives, but also by pure observation. If the agent drives through a red light, we both see it receive a negative reward but also know that it is not the correct behavior. This can be used to your advantage for verifying whether the **policy** your driving agent has learned is the correct one, or if it is a **suboptimal policy**.

## Question 8

1. Please summarize what the optimal policy is for the smartcab in the given environment. What would be the best set of instructions possible given what we know about the environment? *You can explain with words or a table, but you should thoroughly discuss the optimal policy.*
2. Next, investigate the 'sim\_improved-learning.txt' text file to see the results of your improved Q-Learning algorithm. *For each state that has been recorded from the simulation, is the **policy** (the action with the highest value) correct for the given state? Are there any states where the policy is different than what would be expected from an optimal policy?*
3. Provide a few examples from your recorded Q-table which demonstrate that your smartcab learned the optimal policy. Explain why these entries demonstrate the optimal policy.
4. Try to find at least one entry where the smartcab did *not* learn the optimal policy. Discuss why your cab may have not learned the correct policy for the given state.

Be sure to document your state dictionary below, it should be easy for the reader to understand what each state represents.

**Answer: (1)** As per my understanding, below could be an Optimum policy - "if - moving in the direction of waypoint is not violating traffic laws : then Move in the direction of waypoint. else - do not move." Above steps should be taken in minimum possible time.

It suggests a good view of desired output of a self driving car, keeping real world situation in mind.

Below is more descriptive version of policy :

*if oncoming is None then :*

```
if waypoint is right & light is red & right is none : Then Move to Right
if waypoint is right & light is green : Then Move to Right
```

```
if waypoint is forward & light is red : Then Do not move
if waypoint is forward & light is green : Then move forward
```

```
if waypoint is left and light is red : Then do not move
if waypoint is left and light is green : Then move left
```

*else : Do not move*

**(2)** There are many cases where policy is correct for given state, and there are cases where policy is not correct too.

**(3)** Below is an example from "sim\_improved-learning.txt" where agent has learned the correct policy -

('forward', 'green', None, 'right') -- forward : 1.34 -- right : 0.46 -- None : -4.20 -- left : -19.39

In this case , waypoint is 'forward' and light is green with oncoming traffic & no traffic from left. So Forward movement gets a positive reward, taking no action gets negative reward, taking left takes massive negative reward.

**(4)** Below is an example where can did not learn an optimal policy :

--Suboptimal ('right', 'red', 'left', 'forward') -- forward : 0.00 -- right : 2.13 -- None : 0.29 -- left : 0.00

Here - the smartcab has violated traffic rule and positive reward is given for taking right turn in red light also. This might have happened because of deadline criteria, where reward for reaching destination would have been more than violating law.

**State Dictionary :** I tried with below state dictionary for default Q learning Agent and improved Q learning agent : state = (waypoint, inputs['light'], inputs['left'], inputs['oncoming'])

---

## Optional: Future Rewards - Discount Factor, 'gamma'

Curiously, as part of the Q-Learning algorithm, you were asked to **not** use the discount factor, 'gamma' in the implementation. Including future rewards in the algorithm is used to aid in propagating positive rewards backwards from a future state to the current state. Essentially, if the driving agent is given the option to make several actions to arrive at different states, including future rewards will bias the agent towards states that could provide even more rewards. An example of this would be the driving agent moving towards a goal: With all actions and rewards equal, moving towards the goal would theoretically yield better rewards if there is an additional reward for reaching the goal. However, even though in this project, the driving agent is trying to reach a destination in the allotted time, including future rewards will not benefit the agent. In fact, if the agent were given many trials to learn, it could negatively affect Q-values!

## Optional Question 9

*There are two characteristics about the project that invalidate the use of future rewards in the Q-Learning algorithm. One characteristic has to do with the Smartcab itself, and the other has to do with the environment. Can you figure out what they are and why future rewards won't work for this project?*

**Answer:**

**Note:** Once you have completed all of the code implementations and successfully answered each question above, you may finalize your work by exporting the iPython Notebook as an HTML document. You can do this by using the menu above and navigating to **File -> Download as -> HTML (.html)**. Include the finished document along with this notebook as your submission.
